### Abstract

Bachev, H., B. Ivanov, D. Toteva and E. Sokolova, 2017. Agrarian sustainability in Bulgaria – economic, social and ecological aspects. *Bulg. J. Agric. Sci.*, 23 (4): 519–525

The sustainable development has become a major topic not only for the economic science but in the economic policy development. There is a substantial literature dedicated to analyzing the different aspects of sustainability – economic, social and/or ecological. Agriculture has been recognized as one of the economic fields that has multidimensional impact not only on the incomes and well-being of the employed, but also on the rural population as a whole and the environment. This article presents a holistic approach for assessing agrarian sustainability in Bulgaria based on its economic, social and ecological aspects on sectoral macro-level. It is based on official statistical and other information as well as on expert evaluation. Our study has found that the Bulgarian agriculture on macro-level has *good* sustainability. Some of the sustainability aspects have higher levels (e.g. the economic aspect) while others (social and environmental) are inferior. Study results could help in focusing the political efforts, so that the agrarian sustainability, in its social and ecological aspect, could be increased. However a further research is needed to evaluate the level of sustainability at micro-level, so that the major issues and problem areas are addressed accordingly.

**Key words:** agrarian sustainability; sustainability indicators; economic; social; ecological aspects; Bulgarian agriculture

### Introduction

In the world literature, the question of assessing agrarian sustainability is among the most discussed by scientists, policy makers, farmers and stakeholders (Andreoli and Tel-larini, 2000; Bachev, 2005; Bastianoni et al., 2001; FAO, 2013; Häni et al., 2006; Sauvenieret al., 2005; OECD, 2001). The agrarian sustainability has usually been assessed at national or international level (FAO, 2013; OECD, 2001) and usually it is described as ability to satisfy a diverse set of goals through time (Brklacich et al., 1991; Hansen, 1996) or the ability to maintain or improve its functions (Lopez-Ridaura et al., 2002). Often the term sustainability is wrongly associated only with preserving the environment and productivity of the agricultural resources but in our research we consider that agriculture is sustainable if it could maintain

*its economic, ecological and social functions in a long-term* (Bachev, 2010; Bachev et al., 2016).

There is a substantial literature dedicated to analyzing the different aspects of sustainability – economic, social and/or ecological. These three aspects are related to multiple functions of modern agriculture; they are equally important and have to be always accounted for. Agriculture is sustainable if it is: *economically viable and efficient; socially responsible regarding farmers, workers, other agents, communities, consumers and society; and ecologically sustainable* (Bachev et al., 2016).

The agrarian sustainability is a topic of great interest in Bulgaria, as well, and it has been subject of studies, mainly focusing on the sustainability of the agrarian holdings and/or specific activities or sectors (Bachev, 2016; Ivanov et al., 2012). However, this is the first attempt to make a comprehen-

\*Corresponding author: emilia.sokolova@iae-bg.com

hensive assessment of the sustainability of the Bulgarian agriculture on a sectoral macro-level embracing its three aspects.

This article presents a holistic approach for assessing agrarian sustainability based on its economic, social and ecological aspects on sectoral macro-level. It is based on official statistical and other information as well as on expert evaluation. *Its aim* is to estimate the sustainability index for each one of the tree main aspects and to identify the critical areas that lead to improving the level of agrarian sustainability in Bulgaria.

## Materials and Methods

The evaluation of Bulgarian agrarian sustainability is based on a methodology developed for comparative analysis of governance systems and sustainability levels in Bulgarian and Chinese agriculture which is presented in details in our

previous publication (Bachev et al., 2017).

The system for assessing agrarian sustainability includes properly formulated and selected principles, criteria, indicators and reference values for each of them (Table 1). The principles are the highest level which expresses the state of sustainability within the three major aspects – economic, social and ecological. The criteria are more specific than principles and are related to indicators which express the state of agricultural sector assessed when the relevant principle is realized. The indicators are quantitative and qualitative variables from a different type, for example behavior, business, investment, outcome, impact which can be valued and allow the measurement of correspondence with a criteria, giving idea of sustainability in all its aspects. Reference values are the desired values such as absolute, relative or quality of each of the indicators for specific conditions of Bulgarian agriculture which assist the evaluation and give direction to improve/achieve sustainability (Bachev et al., 2017).

**Table 1**

**Principles, criteria and indicators for assessment of Bulgarian agrarian sustainability at sectoral level**

| Principles                           | Criteria   | Indicators  | Reference value   |
|--------------------------------------|--|---|---|
| 1                                    | 2  | 3   | 4   |
| <b>Economic Aspect</b>               |  |   |   |
| Financial stability                  | Reducing dependence on subsidies<br>Sufficient liquidity<br>Minimizing dependence on external capital<br>Positive or high profitability                              | Share of direct payments in Net Income<br>Stocks<br>Ratio of assets growth to interest paid<br>Cost – effectiveness<br>Profitability of capital   | EU average level<br>EU average level<br>EU average level<br>EU average level<br>EU average level          |
| Economic effectiveness               | Maximize or increase labour productivity<br>Maximize or increase land productivity<br>Maximize or increase livestock productivity                                    | Labour productivity<br>Productivity of land<br>Livestock productivity   | EU average level<br>EU average level<br>EU average level  |
| Competitiveness                      | Support or increase of marketed output<br>Support or increase of sales   | Share of imported product in the total agriculturalproduct<br>Gross Value Added (GVA) change  | EU average level<br>EU average level  |
| Adaptability to economic environment | Sufficient adaptability to market environment<br>High investment activity  | Ratio of factor income to fixed costs<br>Growth of long-term assets   | EU average level<br>EU average level  |
| <b>Social Aspect</b>                 |  |   |   |
| Welfare of employed in agriculture   | Equality of income with other sectors<br>Fair distribution of income in agriculture<br>Sufficient satisfaction from farm activity<br>Satisfactory working conditions | Ratio of agricultural income to the average income in the country<br>Variation of payment of hired labour to factor income<br>Variation of employed in agriculture to the entire population<br>Correspondence to official norms | National economy average level<br>National economy average level<br>EU average level<br>Expert assessment |

**Table 1**

| 1                                      | 2  | 3   | 4                |
|--|--|---|------------------|
| Conservation of farming                | Preservation of the number of family farms   | Number of family farms  | EU average level |
|  | Average age of managers  | Share of family labour to all employed  | EU average level |
|  | Share of trained farmers   | Average age of managers   | EU average level |
| Gender equality                        | Increasing the knowledge and skills  | Share of the managers with secondary and higher education   | EU average level |
|  | Equality in men-women relations  | Share of female farm managers   | Program target   |
| Social capital                         | Participation in professional associations and initiatives                               | Share of hired labour members of labour unions  | EU average level |
|  | Contribution to the development of regions and communities                               | Share of farm population in general population  | EU average level |
| Adaptability to the social environment | Sufficient ability to respond to the ceasing farming activity and the demographic crisis | Change in gross fixed capital formation to the change in the number of people employed in agriculture       | EU average level |
| Ecological Aspect                      | Maintaining and improving air quality  | Reduction of CO2 emissions  | Scientific norms |
|  | Minimizing soil losses   | Soil water erosion index  | Scientific norms |
|  | Preservation and improvement of soil fertility   | Soil wind erosion index   | Scientific norms |
|  | Maintaining a balanced land use structure  | Amount of nitrogen fertilization  | Scientific norms |
|  | Preservation of landscape features   | Amount of phosphorus fertilization  | Scientific norms |
| Land quality                           |  | Share of arable land (without fallow) in total agricultural areas   | Program targets  |
| Water quality                          |  | Amount of area covering the requirements for “green” direct payments through maintaining landscape elements | Program targets  |
|  | Maintaining and improving water quality  | Index of groundwater pollution  | Scientific norms |
| Effective energy consumption           | Minimizing the use of conventional energy  | Fuel consumption per unit area  | Scientific norms |
| Biodiversity                           | Maintaining or enhancing natural habitats  | Change in the number of habitats  | Program targets  |
| Animal welfare                         | Compliance with the principles of animal welfare   | Share of agricultural land in NATURA 2000 and other protected areas   | Program targets  |
| Organic production                     | Increasing the organic production  | Level of compliance with the principles of animal welfare   | Program targets  |
| Adaptability to the environment        | Sufficient adaptability to climate change  | Share of areas under conversion or certified for organic production   | EU average level |
|  |  | Variation in the yield of main crops  | EU average level |
|  |  | Share of production losses in gross output in livestock sector  | EU average level |

Source: based on Bachev et al., 2016

Information for each indicator is gathered from official sources – EUROSTAT, DG Agriculture and rural development, National Statistical Institute, Department “Agrostatistics” at the MAF, Ministry of environment and waters. For some of the indicators expert assessment is used.

Very often individual indicators for each Criteria, Principles and Aspect of sustainability are with unequal number that requires an integration of indicators (Table 1). For the integral assessment of sustainability for every Criterion, Principle, and Aspect, and the Overall level, equal weights are used for each Principle in a particular Aspect, and for each Criterion in a particular Principle, and for each Indicator in a particular Criterion.

The *Integral Index* for a particular Criterion ( $IS_c$ ), Principle ( $IS_p$ ), Aspect of sustainability ( $IS_a$ ) or Overall level ( $IS_o$ ) is an *arithmetic average of relevant Indicators and Indices*:

$$IS_c = \sum IS_i/n \quad (n - \text{number of Indicators})$$

$$IS_p = \sum IS_c/n \quad (n - \text{number of Criteria})$$

$$IS_a = \sum IS_p/n \quad (n - \text{number of Principles})$$

$$IS_o = \sum IS_a/3$$

On the basis of the indicators value and the reference value for each indicator sustainability score is calculated. The score could fall within one of six groups, presented in Table 2. These groups are applied also for the interpretation of the Integral Sustainability Index.

The primary level for calculating Integral indexes is the indicator sustainability score determined by the reference values. The reference values for each indicator have two thresholds (binary vector method). The lower threshold on which the indicator sustainability score is determined 0 (unsustainable) and an upper threshold, where the reference value complied to sustainability score up to 1 set up using the expert judgment, average numbers, trends, scientific norms, etc.

**Table 2**

**Limits for grouping of integral assessments of agrarian sustainability**

| Sustainability Index | Sustainability level        |
|----------------------|-----------------------------|
| 0.91 – 1             | Very High Sustainability    |
| 0.71 – 0.90          | High Sustainability         |
| 0.51 – 0.70          | Good Sustainability         |
| 0.31 – 0.50          | Moderate Sustainability     |
| 0.11 – 0.30          | Insufficient Sustainability |
| 0 – 0.10             | Unsustainable               |

## Results and Discussion

Evaluating the different aspects of the Bulgarian agrarian sustainability is based on the developed methodology and a set of selected indicators. The focus in the research is evaluating the level of sustainability within the three main aspects – economic, social and ecological, and identifying the critical elements. Based on the indicators value within the three aspects an integral sustainability score is also calculated. The integral sustainability index of the Bulgarian agriculture is 0.58. That means that the Bulgarian Agrarian Sustainability could be defined as *Good*. However there are still a lot of opportunities for improvement in future, because the index is closer to the lower group. That also requires understanding of the factors leading to this result and the respective role of each aspect for the Overall Sustainability of the Bulgarian agriculture.

Every aspect of agrarian sustainability has its principles, criteria and indicators that help calculating the total sustainability level of the Bulgarian agriculture. The value of each indicator on sectoral level was transformed into Sustainability Index. Principles are the highest hierarchical level associated with the multiple functions of agriculture – economic, social and ecological.

Our assessment has found out that the Economic sustainability of the Bulgarian agriculture is *Good* (index of sustainability 0.7). This aspect has been evaluated on the basis of four major principles – Financial stability, Economic effectiveness, Competitiveness and Adaptability. The lowest integral score is for the Economic effectiveness principle – 0.47 (Figure 1). Each of these principles has different criteria and indicators that are used for calculating the sustainability score.

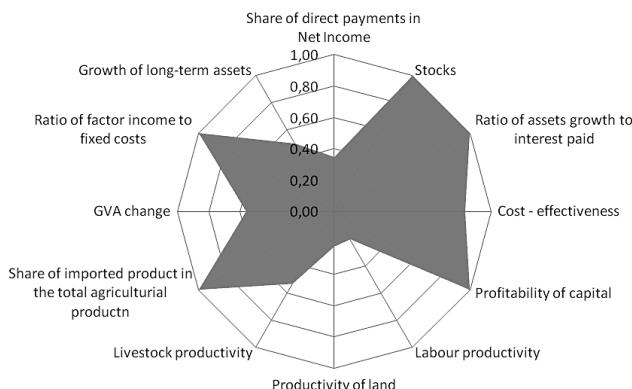

Twelve indicators are used to calculate the sustainability score of each one of the eleven criteria for the four principles

**Fig. 1. Indexes of sustainability for the major principles within the Economic aspect of agrarian sustainability**

Source: own calculations, based on NSI, Agrostatistics department

of economic sustainability. Figure 2 presents the sustainability scores of the different indicators. The index of *Economic effectiveness* sustainability has been calculated on the basis of 5 indicators – *Cost-effectiveness; Profitability of capital; Labour productivity; Productivity of land; and Livestock productivity.*

**Fig. 2. Indicators of economic sustainability of Bulgarian agriculture**

Source: own calculations, based on NSI, Agrostatistics department

Bulgarian agriculture is characterized by low labour, land and livestock productivity. This is due to different factors. The labour productivity in Bulgaria is lower than the EU average not only in the agriculture, but in the other economic sectors as well. That is due usually to low or old technology use, low labour quality, lack of qualification, lower motivation due to insufficient payment, aging labour force and other socio-economic factors. The labour productivity affects the economic effectiveness, but it is also strongly connected with the social aspects of the agrarian sustainability.

The land productivity of the Bulgarian agriculture is also on unsatisfactory level. The gross output per hectare in Bulgaria for the major arable crops is well below the EU average and it varies from year to year. The sustainability score for the livestock productivity is higher, but it is still only on *Good* level and it needs to be improved in order to ensure higher economic sustainability for the Bulgarian agriculture. Other indicators that show low or only *Moderate* sustainability levels are the Share of direct payments in the net income (0.35) and the Growth of the long term assets (0.50). *Good* is the sustainability score of the GVA change (0.53). These indicators demonstrate the high dependency of the Bulgarian agriculture on government transfers through the direct payments. In case these transfers are decreased or they stop this would affect the financial stability of the Bulgarian agriculture. Insufficient

increase in the GVA of the Bulgarian agriculture and small rate of investment growth affects its long term economic sustainability negatively.

The Social and Ecological sustainability of the Bulgarian agriculture are assessed as *Good* (the score for both of them is 0.53). The assessment of the Social aspect of the agrarian sustainability is based on five principles: *Welfare of employed in agriculture; Conservation of farming; Gender equality; Social capital; and Adaptability to the social environment.* Each of these principles is evaluated based on set of criteria and indicators. The lowest level has the sustainability index for the *Social capital* principle, the Gender equality principle and the Welfare of the employed in agriculture (Figure 3).

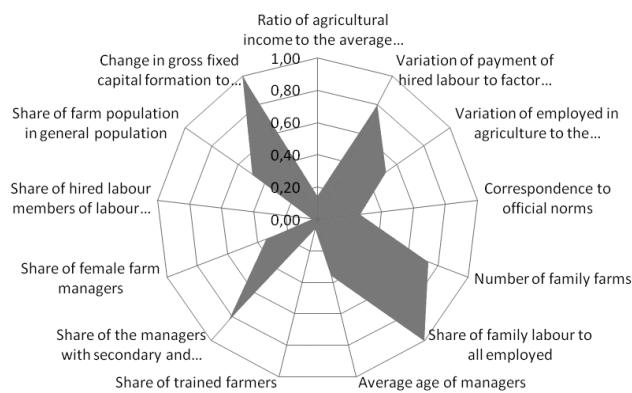

**Fig. 3. Indexes of sustainability for the major principles within the Social aspect of agrarian sustainability in Bulgaria**

Source: own calculations, based on NSI, Agrostatistics department

The indicators used to assess the sustainability (Figure 4) of the Welfare of employed in agriculture are: Ratio of agricultural income to the average income in the country; Variation of payment of hired labour to factor income; Variation of employed in agriculture to the entire population; Correspondence to official norms. While there is no big variation of the *Payments of the hired labor to the factor income* (the sustainability score of this indicator is 0.8 which mean High sustainability) and *Variation in the number of employed* (0.52 sustainability score which denotes Good sustainability), the other two indicators have low sustainability score – *Ratio of agricultural income to the average income in the country* has a score of only 0.15 and *Correspondence to official norms* – 0.27 that means they have Insufficient sustainability.

Higher sustainability score has the *Conservation of farming* principle, although the *share of trained farms* is very low. Its sustainability score is only 0.06. This indicator emphasizes a specific problem that need and should be addressed. More

**Fig. 4. Indicators of social sustainability of Bulgarian agriculture**

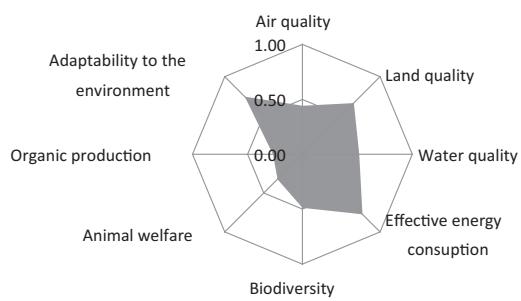

Source: own calculations, based on NSI, Agrostatistics department

employed in the agriculture should receive training and possibilities to develop their skills and knowledge in order to increase the sustainability of the agricultural sector. One of the problems is that a big percent of the employed are seasonal workers that could not be trained specifically for a certain job or operation.

Gender inequality is another major issue that Bulgarian agriculture faces and which leads to low score for the *Equality* principle. Based on data of the share of women farm managers the indicator value suggests that there is inequality. The percentage of women on managerial positions is low, as well as the number of women that own agriculture businesses. However, the women are active members of the rural community which could in future increase their decision-making roles.

The highest is the value of the Index of adaptability to the social environment. Having in mind the changing social structure, the decline in the number of employed in agriculture, as well as the demographic crisis in the rural areas, there is a positive trend in the ratio of gross fixed capital formation to labour availability. That means that the shortage of labour could be successfully resolved with more capital formation.

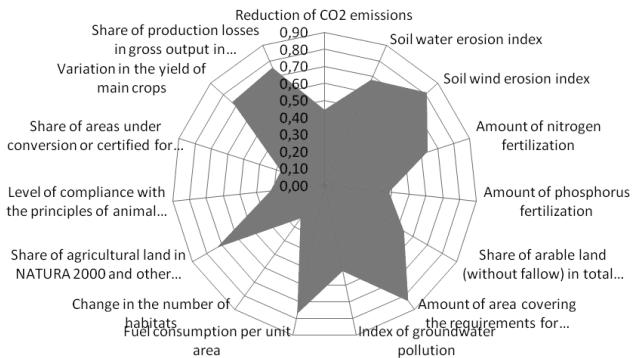

The *Environmental sustainability* of the Bulgarian agriculture is assessed as *Good* with a score of 0.53. This is the aspect with most diverse indicators covering eight principles of environmental sustainability (Figure 5). The highest level of sustainability has been measured for the *Effective energy consumption* (0.77) and the *Adaptability to the environment* (0.74). Concerns stem from the level of the indexes for some of the principles that are critical for ensuring environmental sustainability. Such principles are the *Air quality*, *Biodiversity*, *Animal welfare*, and *Organic production*.

**Fig. 5. Indexes of sustainability for the major principles within the Ecological aspect of agrarian sustainability in Bulgaria**

Source: own calculations, based on NSI, Agrostatistics department, EUROSTAT and reports from MOEW

All this indicators (Figure 6) reveal that there is still much work needed in order to ensure that the agriculture does not harm the environment and the biodiversity. It is important to point out that in several areas the Bulgarian agriculture demonstrates strong sustainability, like the effective energy consumption. It should be made sure that in case of more intensive economic growth these high scoring factors will not deteriorate.

**Fig. 6. Indicators of Ecological sustainability of Bulgarian agriculture**

Source: own calculations, based on NSI, Agrostatistics department, EUROSTAT and reports from MOEW

The agrarian sustainability assessment is important for detecting critical areas that should be addressed by the policy makers in Bulgaria. Previous attempts to assess the agriculture on macro-level haven't been made, but on micro-level Bachev (2017) analyzes the level of sustainability of the Bulgarian farms. According to survey with farm managers the economic sustainability is weaker than the environmental and social at farm level. Our sectoral analyzes gives the op-

posite results – a higher economic sustainability and lower social and ecological. This could be due to several reasons – the different objectives and assessment methodology of studies. While our current assessment is on the sustainability of agriculture, the former study concerns sustainability of diverse farming structures (which is only a part of the sustainability of agrarian sector as a whole). Similarly, data for this study are at national level, from national statistics and are summarized, while farm level data used in referred publication is from survey with farm managers. It is well-known that the managers of agricultural holdings usually consider their economic situation as more important and often identify ecological and social aspects as secondary and therefore consider that these objectives are easier to achieve. Most of the managers in the survey quote that their activity meets almost all ecological and social requirements.

This discrepancy is also a reason to implement a research at the farm level as part of this research project with the same methodology and indicators used at sectoral level. This will allow for full comparability of the results and will provide a picture of the actual differences in the way micro-and macro-level sustainability is assessed and evaluated in agriculture.

## Conclusions

The development of coherent and adequate agricultural and food policies require recognizing the main critical areas that influence negatively the development of sustainable and efficient agriculture. Sustainability is a key concept that will have greater importance in the future, having in mind the problems the world population is facing with the climate and all unexpected effects of its change. Agricultural scientists have recognized the importance of sustainable agrarian development, although there is no universally accepted definition and methodology to assess it.

This article offers methodology and assessment of the different aspects of the Bulgarian agrarian sustainability in its economic, social and ecological aspects. The overall level of sustainability is *Good* (0.58). All the aspects have been assessed as *Good*, but the sustainability index of the economic aspect (0.70) is significantly higher than the indexes of the social and ecological aspects (both 0.53). There are critical areas within each aspect that require specific measures in order to ensure the sustainable development of the Bulgarian agriculture.

Suggested holistic approach will be further experimented at different (subsectoral, ecosystem, regional, farm) levels, improved and ultimately applied for comparative studies of

sustainability levels of Bulgarian and other (Chinese, East European, etc.) agricultures.

## Acknowledgements

This research is part of bilateral research cooperation project between Bulgaria and China on „Governing and Assessment of Agrarian Sustainability – Experiences, Challenges, and Lessons from Bulgaria and China” funded by the Bulgarian Science Fund and the Ministry of Science and Technology of the People’s Republic of China
